Project #1

A search problem is a problem that appears in many different computational problems. I would say almost all problems have some sort of search embedded in them. The two main categories of searches are uninformed and informed, and the difference lies in an uninformed search where there is no knowledge of the goal other than the initial prompt, and an informed search where there is more knowledge of the goal and how to get there which is called a heuristic. For every search problem there are a couple defining characteristics. There is a start state where the problem is initially defined, the state space which is the set of all states, and the goal state where the problem is supposed to end. With many different search problems there are also many different algorithms that try to solve these problems.

Here is the initial prompt given to the user on how to run the program and what each symbol means. I attached it here to assist in the grading process and make it more user friendly. I have never programmed in python before this class, so it was an interesting challenge to tackle.

S - The character S represents the start

G - The character G represents the end

☺ - The smiley face represents the path taken

◼ - The square with the filled in circle represented the open list

☼ - The sun (i think that's what it is) represents the closed list

```
C:\Users\hunte\PycharmProjects\assignment1\Scripts\python.exe C:/Users/hunte/PycharmProjects/assignment1/assignment1.py
The start is represented by S and the end is represented by G
This program is used to give a visual representation of search algorithms
The ◼ symbol represents the open list
The ☼ symbol represents the closed list
The path found by the algorithm is represented by ☺

I noticed with Greedy best first that the Manhattan distance and the euclidean distance generally returned the similar if not the same output for most inputs. The larger the graph gets the more varied their respective outputs get.

Greedy Best First with Minkowski Distance:

```

I never heard of the Minkowski distance prior to this program so I thought it was an interesting one to include in there. The lambda value seems to have a big impact on the efficiency of the search.

A* With Euclidean Distance:

1 = breadth first. 2 = lowest cost. 3 = greedy best first. 4 = A*

4

1 = Euclidean. 2 = Manhattan 3 = Minkowski

Total cost to goal:6
Total steps taken to
Total number of time

```

As with the above greedy algorithms I did not see a huge variation in the results between the A* with Euclidean and A* with Manhattan distance. As the graph grew in size I found slight differences but nothing substantial.

A* with Minkowski Distance:

```
Please enter a number for the type of algorithm to use.
1 = breadth first. 2 = lowest cost. 3 = greedy best first. 4 = A*

```

Conclusion:

Overall I feel my results were consistent with what I was expecting. The search that I would say performed the best overall would be A* with Manhattan or Euclidean distance. Those two searches took a minimum total cost to the goal and a minimum total steps taken to the goal. The greedy best first had the least amount of items added to the open list which makes sense due to it taking a pretty direct path. The lowest cost search had the most total steps taken to the goal

and had the most items on the open list. The breadth first search had the highest total cost to goal and also had a lot of items on the open list. I believe these findings line up with what we learned about the algorithms previously and I personally enjoyed learning and coding the A* algorithm as it seems like an interesting search. I believe all the algorithms worked as desired, unless I am misinterpreting how they are supposed to work. The overall project has been beneficial to my learning by not only starting to learn python but also learning new search algorithms.
